Supporting Information

ABSTRACT: We report a new strategy for fabricating 2D/2D low-resistance ohmic contacts for a variety of transition metal dichalcogenides (TMDs) using van der Waals assembly of substitutionally doped TMDs as drain/source contacts and TMDs with no intentional doping as channel materials. We demonstrate that few-layer WSe₂, field-effect transistors (FETs) with 2D/2D contacts exhibit low contact resistances of ~0.3 kΩ μm, high on/off ratios up to >10⁷, and high drive currents exceeding 320 μA μm⁻¹. These favorable characteristics are combined with a two-terminal field-effect hole mobility μ_FE ≈ 2 × 10⁴ cm² V⁻¹ s⁻¹ at room temperature, which increases to >2 × 10⁵ cm² V⁻¹ s⁻¹ at cryogenic temperatures. We observe a similar performance also in MoS₂ and MoSe₂ FETs with 2D/2D drain and source contacts. The 2D/2D low-resistance ohmic contacts presented here represent a new device paradigm that overcomes a significant bottleneck in the performance of TMDs and a wide variety of other 2D materials as the channel materials in post-silicon electronics.

KEYWORDS: MoS₂, WSe₂, MoSe₂, field-effect transistor, two-dimensional, ohmic contact

The layered nature of transition metal dichalcogenides (TMDs) allows for easy cleavage and formation of ultrathin layers, which are being considered as suitable semiconducting counterparts to semimetallic graphene and may lead to flexible electronics and optoelectronics applications.¹⁻⁵ However, fabrication of high-performance transistors of TMDs including WSe₂, MoS₂, and MoSe₂ has been a major challenge in 2D electronics.⁶,⁷ The performance of current metal-contacted TMDs is limited by the presence of a significant Schottky barrier (SB) in most cases.⁸⁻¹² In silicon-based electronics, low-resistance ohmic contacts are achieved by selective ion implantation of drain/source regions below metal electrodes. In this way, the contact barrier width between the metal electrodes and degenerately doped source and drain regions is significantly reduced. Unfortunately, the ultrathin body of monolayer and few-layer TMDs prohibits effective doping by ion implantation. Various other doping methods such as surface charge transfer doping,⁶,¹³⁻¹⁵ and substitutional doping,¹⁶,¹⁷ have also been developed by different groups during the past few years to reduce the Schottky barrier width and thus reduce the contact resistance of TMD devices. However, most of these doping methods suffer from poor air or thermal stability. In this respect, substitutional doping appears to offer a suitable alternative, since dopants secured by covalent bonding (e.g., Nb doped MoS₂) during the material synthesis yield devices with excellent air and thermal stability.¹⁸ Nevertheless, the limitation of conventional substitutional doping during synthesis is the inability to form a spatially abrupt doping profile, which defines the drain, the channel, and the source regions and which is needed for low power, high-performance electronics.

To date, various innovative strategies to reduce the contact resistance such as use of graphene contacts,⁵,¹⁸⁻²⁰ and phase-engineering,²¹,²² are still deficient as they do not offer true ohmic contact behavior or have insufficient thermal stability. Nearly barrier-free contacts to MoS₂ have been achieved by using graphene as contact electrodes because the Fermi level of graphene can be effectively tuned by a gate voltage to align with the conduction band minimum (CBM) of MoS₂, which minimizes the Schottky barrier height (SBH).²² Still, a significant SBH is usually formed between graphene and WSe₂ because the work function of graphene is close to the middle of the band gap in WSe₂.¹⁸,¹⁹ We have previously used the extremely large electric double layer (EDL) capacitance of an
In this Letter, we present a new strategy that utilizes 2D/2D vertical junctions to engineer low-resistance ohmic contacts, which turn TMDs including WSe2, MoS2, and MoSe2 into high-performance transistors. 2D/2D junctions with atomically sharp interfaces can be created by van der Waals assembly of 2D crystals without the constraints of atomic commensurability.\textsuperscript{58,39} We demonstrate that 2D/2D contacted FETs consisting of an undoped few-layer WSe2 channel and degenerately p-doped WSe2 drain and source contacts exhibit low contact resistances of \(~0.3\, \text{k} \Omega \mu \text{m}\), high on/off ratios up to \(~>10^9\), and high drive currents exceeding \(320\, \mu\text{A} \mu \text{m}^{-1}\). Furthermore, low resistance ohmic contacts achieved in our devices enable the investigation of intrinsic channel properties of TMD materials. Our WSe2 devices with 2D/2D contacts display a two-terminal field-effect hole mobility \(\mu_{\text{FE}} \approx 2.2 \times 10^5\, \text{cm}^2\, \text{V}^{-1}\, \text{s}^{-1}\) at room temperature, which increases to about \(~2.17 \times 10^6\, \text{cm}^2\, \text{V}^{-1}\, \text{s}^{-1}\) at \(~5\, \text{K}\). Similarly, record high two-terminal field-effect hole mobility up to \(~2.8 \times 10^3\, \text{cm}^2\, \text{V}^{-1}\, \text{s}^{-1}\) (at cryogenic temperatures) has been observed in MoS2 and MoSe2 FETs with degenerately p-doped MoS2 contacts formed by van der Waals assembly.\textsuperscript{112}

Figure 1a,b presents a schematic diagram and optical micrograph of a WSe2 FET device composed of degenerately p-doped WSe2 (\text{Nb}_{0.005}\text{W}_{0.995}\text{Se}_2) 2D drain/source electrodes in contact with a 2D WSe2 channel with no intentional doping. Devices containing TMDs such as WSe2 were fabricated by chemically exfoliating the flakes, which can be attributed to the atomically sharp interface between the 1T and 2H phases and to the fact that the work function of the 1T phase is very close to the CBM of the 2H phase.\textsuperscript{21} However, a finite SBH is expected to arise for the hole channel of MoS2 FETs using this phase-engineering contact strategy because of the large offset between the work function of the 1T phase and the CBM of the 2H phase. Furthermore, the 1T phase MoS2 is thermally unstable above \(~100\, \text{°C}\). The availability of a variety of semiconducting TMDs such as MoSe2, WS2, and WSe2 with different band structures and charge neutrality levels offers additional distinct properties and opportunities for device applications.\textsuperscript{56,6,8,9,13,28–37} However, the variation of electron affinity, band gap, and band alignments also presents significant challenges to contact engineering. To unlock the full potential of TMDs as channel materials for high-performance thin-film transistors, highly effective and versatile contact strategies for making low-resistance ohmic contacts are needed.

In this Letter, we present a new strategy that utilizes 2D/2D vertical junctions to engineer low-resistance ohmic contacts, which turn TMDs including WSe2, MoS2, and MoSe2 into high-performance transistors. 2D/2D junctions with atomically sharp interfaces can be created by van der Waals assembly of 2D crystals without the constraints of atomic commensurability.\textsuperscript{58,39} We demonstrate that 2D/2D contacted FETs consisting of an undoped few-layer WSe2 channel and degenerately p-doped WSe2 drain and source contacts exhibit low contact resistances of \(~0.3\, \text{k} \Omega \mu \text{m}\), high on/off ratios up to \(~>10^9\), and high drive currents exceeding \(320\, \mu\text{A} \mu \text{m}^{-1}\). Furthermore, low resistance ohmic contacts achieved in our devices enable the investigation of intrinsic channel properties of TMD materials. **Figure 1.** Design and characteristics of a high-performance WSe2 FET with 2D/2D contacts. (a) Perspective side view of a WSe2 FET with degenerately p-doped WSe2 (\text{Nb}_{0.005}\text{W}_{0.995}\text{Se}_2) contacts. (b) Optical micrograph of the device. The channel region is encapsulated in hexagonal BN (h-BN) from the top and the bottom. (c) Band profiles in the off- and the on-state of the FET with 2D/2D contacts. Holes are injected from a metal (M) into a degenerately p-doped WSe2 contact (C) layer through a highly transparent M/C interface. Hole injection from the drain/source contact (C) layer across the 2D/2D interface into the undoped WSe2 channel is modulated by the gate voltage \(V_{\text{bg}}\). (d) Modulation range of the source-drain current \(I_{\text{DS}}\) by the back-gate voltage \(V_{\text{bg}}\). (e) Linearity of the \(I_{\text{DS}}\) characteristics indicating ohmic behavior for a wide range of back-gate voltages.\textsuperscript{112}
Subsequently, metal electrodes, consisting of 5 nm Ti/50 nm Au, were formed by deposition on top of the degenerately doped TMD contacts (see the Methods and Sections 1 and 2 of the Supporting Information). To preserve its intrinsic electrical properties, the TMD channel material was encapsulated in hexagonal boron nitride (hBN). 15,40 Similar to degenerately doped silicon in Si electronics, ohmic contacts with low contact resistance <0.2 kΩ μm is also achievable between degenerately doped TMDs and the top metal electrodes (see Section 3 of the Supporting Information). Consequently, the total contact resistance critically depends on the resistance of the 2D/2D junctions between the degenerately doped TMDs, acting as source/drain electrodes, and the undoped TMD channel material.

The band diagram and working principle of the 2D/2D contacts are illustrated in Figure 1c. The difference in work function between the undoped channel and the degenerately doped drain/source, caused by the different carrier densities, creates a band offset across the 2D/2D interface. In conventional 3D semiconductor junctions, the band offset is usually well-defined by the covalent bonds at the junction interface. Since the interlayer interaction in 2D TMDs and their junctions is much weaker, the band offset can be electrostatically tuned by a back-gate voltage. 38,39 We take advantage of this unique property of 2D/2D junctions to form spatially sharp, tunable, true ohmic contacts to TMDs.

As seen in the top panel of Figure 1c, there are no free carriers in the channel in the off-state at the back-gate voltage 0 V. Increasing the negative back-gate voltage shifts all bands in the channel material up, whereas the bands in the degenerately doped electrodes are unaffected. The modified band alignment introduces holes in the channel material, as illustrated in the bottom panel of Figure 1c. In the on-state, achieved at gate voltages exceeding the threshold (Vbg > 0 V), the contact barrier at the interface essentially vanishes, leading to a low-resistance contact.

Figure 1d,e shows the room-temperature transfer and output characteristics of a five-layer WSe2 FET that is encapsulated in hBN. This ~3.5 nm thick device is contacted by degenerately p-doped WSe2 (Nb0.005W0.995Se2) and measured using a Si back gate. The gate dielectric consists of 40 nm thick hBN on 280 nm thick SiO2. It shows clear p-type behavior with an exceptionally high on/off ratio exceeding 105 at Vds = −1 V and a subthreshold swing of ~460 mV/dec, which can be further reduced to the near-ideal value of ~63 mV/dec by using a top gate with hBN gate dielectric (see Section 5 of the Supporting Information). The gate voltage range can also be significantly reduced by using thinner and high-κ dielectrics.

The high on/off ratio can be partially attributed to the significant enhancement of the on-current that is enabled by the low-resistance 2D/2D contacts. As shown in Figure 1e, the on-state drain current is linear at all back-gate voltages, indicating ohmic behavior. Although we present results on p-type TMD transistors in this work, we have also achieved n-type behavior using heavily n-doped TMDs as drain and source contacts (see Section 6 of the Supporting Information). This is an important advantage of the proposed 2D/2D contact strategy because availability of both p-type and n-type 2D transistors with low-resistance ohmic contacts is crucial for CMOS applications.

We quantify the contact resistances of the 2D/2D contacts using the transfer length method (TLM). Figure 2a,b shows the schematic diagram and an optical micrograph of a WSe2 test structure for TLM measurements, consisting of an ~7 nm thick undoped WSe2 channel, outlined by the dash-dotted lines, connected to ~21 nm thick p-doped WSe2 (Nb0.005W0.995Se2) drain and source contacts with varying gap spaces, outlined by the dashed lines. From the y intercept of the linear fit on the vertical axis yields the contact resistance 2Rc. (d) Output characteristics of the shortest channel (L ≈ 0.27 μm) in the TLM structure. The maximum current exceeds 320 μA/μm at Vds = −1.5 V and Vbg = −130 V.
Figure 3. Observation of intrinsic channel properties in WSe$_2$ (a,c) and MoS$_2$ (b,d) devices with 2D/2D contacts. (a) Temperature-dependent two-terminal conductivity $\sigma$ of WSe$_2$ as a function of the back-gate voltage $V_{bg}$ at $V_{ds} = -50$ mV. The WSe$_2$ channel is $\sim 3.5$ nm thick, 14.8 $\mu$m long and a 4.7 $\mu$m wide. Inset: temperature dependence of $\sigma$ at gate voltages ranging from $-30$ V to $-80$ V in steps of $-5$ V. A metal–insulator transition (MIT) is observed at $\sim e^2/h$ as indicated by the dashed line. (b) Temperature-dependent two-terminal conductivity $\sigma$ of MoS$_2$, as a function of $V_{bg}$ at $V_{ds} = -10$ mV. The MoS$_2$ channel is $\sim 6.8$ nm thick, 13.0 $\mu$m long and a 2.7 $\mu$m wide. Inset: conductivity within the MIT region on an expanded scale. (c,d) Two-terminal field-effect hole mobilities $\mu_{FE}$ in WSe$_2$, (c) and MoS$_2$ (d) as a function of temperature. The maximum values observed in two-terminal measurements are $\mu_{FE} \approx 2.0 \times 10^3$ cm$^2$ V$^{-1}$ s$^{-1}$ in WSe$_2$ and $\mu_{FE} \approx 2.8 \times 10^3$ cm$^2$ V$^{-1}$ s$^{-1}$ in MoS$_2$ at cryogenic temperatures. The linearity of the output characteristics of WSe$_2$ and MoS$_2$ devices, shown in the insets of (c,d), indicates the absence of Schottky barriers in the contact region.

Large drive currents exceeding 320 $\mu$A $\mu$m$^{-1}$, which are comparable to the highest drive currents achieved in few-layer TMD devices. It is worth noting that even at the large values $V_{bg} = -130$ V and $V_{ds} = -1.5$ V, $I_{ds}$ has not yet reached saturation, which indicates that still higher drive currents should be achievable.

Low-resistance 2D/2D contacts also enable us to investigate the intrinsic properties of the channel. Figure 3a presents the temperature-dependent two-terminal conductivity of another WSe$_2$ device that is 3.5 nm thick, $\approx 14.8$ $\mu$m long, $\approx 4.7$ $\mu$m wide, and passivated by h-BN. The two-terminal conductivity is defined by $\sigma = I_{ds}/V_{ds} \times L/W$, where $L$ is the length and $W$ the width of the channel. With increasing hole concentration, the WSe$_2$ device displays a crossover from an insulating regime, where the conductivity increases with increasing temperature, to a metallic regime, where the conductivity decreases with increasing temperature. This metal–insulator–transition (MIT) can be more clearly seen in the corresponding temperature-dependent conductivity, displayed in the inset of Figure 3a, and occurs at a critical conductivity of $\sim e^2/h$, consistent with the MIT observed previously in MoS$_2$, MoSe$_2$, and WSe$_2$. The MIT observed here is unlikely a hysteretic effect because the transfer curves measured with opposite gate-sweeping directions overlap to a large degree (see also Section 7 of the Supporting Information). As seen in the inset of Figure 3c, the output characteristics of the device remain linear down to 5 K, confirming a true ohmic contact at the 2D/2D interface that is free of a Schottky barrier. Consequently, the on-state conductivity at $V_{bg} = -80$ V increases monotonically by a factor of $\sim 6$ as the temperature decreases from 300 to 5 K. The temperature-dependent field-effect hole mobility of the WSe$_2$ device is shown in Figure 3c. The values have been extracted from the linear region of the conductivity curves in the metallic state at $-80$ V $< V_{bg} < -50$ V using the expression $\mu_{FE} = (1/C_{bg}) \times (dV_{ds}/dV_{bg})$, where $C_{bg}$ is the geometric back-gate capacitance of 27 nm thick hBN on 285 nm thick SiO$_2$ based on the parallel plate capacitor model. This geometric capacitance is consistent with the back-gate capacitance of a similarly hBN-encapsulated WSe$_2$ Hall bar device determined by Hall measurement (see Section 8 of the Supporting Information). As the temperature decreases from room temperature to 5 K, the hole mobility for the WSe$_2$ device increases from $\sim 2.2 \times 10^3$ cm$^2$ V$^{-1}$ s$^{-1}$ to about $2.1 \times 10^3$ cm$^2$ V$^{-1}$ s$^{-1}$. This mobility increase with decreasing temperature, along with the large mobility values, suggests strongly that the hole transport in the device is limited by phonons in the channel.

Next, we demonstrate that the 2D/2D contact strategy can also be used to achieve low-resistance contacts for the hole channel of MoS$_2$ FET devices, which has been a major challenge because hole injection across the metal/MoS$_2$ interface has been obstructed by a large Schottky barrier.

Figure 3b shows the two-terminal conductivity of an MoS$_2$ FET device consisting of a 6.8 nm thick MoS$_2$ channel with no intentional doping, contacted by degenerately p-doped MoS$_2$ (Ni$_{0.005}$Mo$_{0.995}$S$_2$) drain and source electrodes. In contrast to MoS$_2$ devices with conventional metal contacts, which overwhelmingly displays n-type behavior, the above MoS$_2$ device exhibits p-type behavior. The temperature-dependent conductivity of the p-type MoS$_2$ device also shows an MIT, as seen in the inset of Figure 3b. We observe an $\sim 13$-fold increase of the on-state conductivity as the temperature decreases from
Figure 4. Characteristics and working principle of p-type field-effect transistors with 2D/2D heterocontacts. (a) Ohmic behavior observed in output characteristics of a MoSe2 device with degenerately p-doped MoS2 (Nb0.005Mo0.995S2) drain/source contacts at 80 K, where the MoSe2 channel is \( \sim 6.2 \) nm thick, 12.3 \( \mu \)m long, and a 5.5 \( \mu \)m wide. (b) Nonohmic behavior displayed by MoSe2 devices with degenerately p-doped WSe2 (Nb0.005W0.995Se2) drain/source contacts at 80 K, where the MoSe2 channel is \( \sim 5.0 \) nm thick, 6.3 \( \mu \)m long, and a 2.1 \( \mu \)m wide. (c) Two-terminal conductivity \( \sigma \) in the MoSe2 device of (a) with p-doped MoS2 contacts as a function of back-gate voltage \( V_{bg} \) at different temperatures and \( V_{ds} = -10 \) mV. Inset: two-terminal field-effect hole mobility as a function of temperature in the MoSe2 device contacted by p-doped MoS2. (d) Conductivity \( \sigma \) in the MoSe2 device of (b) with p-doped WSe2 contacts as a function of \( V_{bg} \) at different temperatures and \( V_{ds} = -50 \) mV. (e,f) Changes in lateral band profiles induced by forming optimum 2D/2D heterojunctions in MoSe2 contacted by p-doped MoS2 (e) and p-doped WSe2 (f).

300 to 5 K and linear output characteristics down to 5 K, depicted in the inset of Figure 3d, indicating a barrier-free contact with a low contact resistance. The larger negative threshold voltage observed in our p-type MoS2 than in p-type WSe2 FETs can be attributed to the higher surface Zeeman effect in the MoS2 channel material. As seen in Figure 3d, the field-effect hole mobility of the MoS2 device increases from \( \sim 1.8 \times 10^3 \) \( cm^2 V^{-1} s^{-1} \) to about \( 2.8 \times 10^3 \) \( cm^2 V^{-1} s^{-1} \) as the temperature decreases from room temperature to 5 K. To the best of our knowledge, the low-temperature mobility values observed in our p-type WSe2 and MoS2 devices represent a record high two-terminal mobility values in few-layer TMDs, which can be attributed to both low-resistance 2D/2D ohmic contacts and hBN channel passivation.

To further demonstrate the versatility of the new contact paradigm and to elucidate the nature of 2D/2D contacts, we also investigated TMD devices with 2D/2D heterocontacts, where the drain/source electrodes and the channel consist of different TMD materials. Figure 4a,b presents the output characteristics of representative devices consisting of an MoSe2 channel and degenerately p-doped MoS2 (Nb0.005Mo0.995S2) and WSe2 (Nb0.005W0.995Se2) drain/source contacts, measured at 80 K. Whereas the MoSe2 device in Figure 4a with p-doped MoS2 contacts shows linear output characteristics indicative of ohmic behavior, the MoSe2 device in Figure 4b with p-doped WSe2 contacts displays a strongly nonlinear behavior. The nonlinearity and reduction of \( I_{th} \) suggest the presence of a significant contact barrier in this case. Figure 4c,d presents two-terminal conductivity as a function of gate voltage for the same devices at different temperatures. The MoSe2 device with p-doped MoS2 contacts exhibits a similar behavior as the WSe2 and MoS2 devices presented in Figure 3. This similarity includes the presence of an MIT, an increase in on-state conductivity, measured at \( V_{bg} = -100 \) V and \( V_{ds} = -10 \) mV, by a factor of \( \sim 19 \) as the temperature decreases from 300 to 5 K. As seen in the inset of Figure 4c, the phonon-limited two-terminal mobility increases from \( \sim 1.0 \times 10^2 \) \( cm^2 V^{-1} s^{-1} \) at 300 K to about \( 2.4 \times 10^3 \) \( cm^2 V^{-1} s^{-1} \) at 5 K. In sharp contrast, the two-terminal conductivity in the MoSe2 device with p-doped WSe2 drain/source contacts decreases rapidly as the temperature decreases from 240 to 80 K, indicating contact-limited charge transport.
charge redistribution. Because hole accumulation in region II does not hinder hole transport, ohmic behavior is observed. In the case where the VBM of the MoSe₂ channel is below the VBM of p-doped WSe₂ drain/source contacts, a downward band bending occurs in the lateral interface region II, which is accompanied by a flow of holes away from this lateral interface region. The hole depletion in region II acts as a barrier hindering hole transport, leading to nonohmic behavior. We obtained consistent results in multiple p-type TMD FETs with 2D/2D heterocontacts: ohmic contacts are formed when the VBM of the channel material is above the VBM of the contact material and nonohmic behavior occurs when the VBM of the channel material is below that of the contact material. (see Sections 10 and 11 of the Supporting Information).

In summary, we have developed a novel 2D/2D contact strategy to achieve high-quality ohmic contacts for MoSe₂, MoS₂, and WSe₂ FETs. The low-resistance ohmic contacts lead to drastically improved device performance, including on/off ratios up to >10⁶, drive currents >320 μA μm⁻¹, and two-terminal extrinsic field-effect mobilities up to 2.8 × 10⁶ cm² V⁻¹ s⁻¹ at cryogenic temperatures. The newly developed contact engineering approach is applicable to a wide range of 2D materials for both p-type and n-type transistors, which are compatible with conventional semiconductor processes, and may be implemented in roll-by-roll production of flexible electronics with the development of large scale synthesis techniques.

**Methods.** All crystals of degenerately doped and undoped TMDs used in this work were synthesized by chemical vapor transport except for undoped MoS₂ crystals, which were purchased from SPI Supplies. Optical microscopy and Park-SystemsXE-70 noncontact mode atomic microscopy (AFM) were used to identify and characterize thin TMD flakes. To fabricate TMD devices with 2D/2D contacts, thin flakes of degenerately doped and undoped ultrathin TMDs were mechanically exfoliated from bulk crystals. The degenerately doped TMD flakes, forming the drain and source electrodes, were then artificially stacked using a dry transfer method on top of undoped TMDs flakes, which form the channel. Metal electrodes were then fabricated on top of the degenerately doped source and drain contact regions by standard electron beam lithography and subsequent deposition of 5 nm of Ti and 50 nm of Au (see also Section 2 of the Supporting Information).

Electrical properties of the devices were measured by a Keithley 4200 semiconductor parameter analyzer in a Lakeshore Cryogenic probe station under high vacuum (1 × 10⁻⁶ Torr) or in a Quantum Design PPMS.
