Experimental details:

**Synthesis:** MWCNTs were produced by chemical vapor deposition (CVD) using Co/Fe-Al$_2$O$_3$ as catalysts, with ethylene as carbon source and purified. The purified MWCNTs were heated at 500°C for 30 min under an air atmosphere to open the caps. The open-ended MWCNTs were degassed for one day with interval flame heating and then sealed in the presence of extra red phosphorus (Aladdin, 99.999% metals basis) under a vacuum of 10$^{-5}$ Pa in an H-shaped Pyrex tube. The H-shaped Pyrex tube was then heated to 500°C for 48 h at a heating rate of 1°C/min and then cooled down in oven or under a temperature gradient condition (one end about 50~100°C lower than the other end where the MWCNTs were present).

**Raman:** Raman spectroscopy was taken in a back-scattering geometry using a single monochromator with a microscope (Reinishaw inVia), which was equipped with a CCD array detector (1024 × 256 pixels, cooled to -70°C) and an edge filter. The Raman spectra were recorded at a power of 0.49-7.0 mW for 100-500 s with excitation lasers at 514 and 633 nm. The spectral resolution and reproducibility was determined to be better than 0.1 cm$^{-1}$.

**FTIR:** ATR-FTIR was performed by a BRUKER/TENSOR27 spectrometer using Single Reflection ATR by PIKE Technologies. The spectra were obtained with a spectral resolution of 4 cm$^{-1}$ for 1000 scans.
